Metal-Organic Frameworks, Amide, Adsorption, Separation, Breakthrough

ABSTRACT: Here we report the use of a pillaring strategy for the design and synthesis of three novel amide-functionalized metal-organic frameworks (MOFs), **TMUs-22/-23/-24**, isorecticular to the recently reported imine-functionalized **TMU-6** and **TMU-21** MOFs. An extensive study of their CO₂ sorption properties and selectivity for CO₂ over N₂, from single gas sorption isotherms to breakthrough measurements, revealed that not only the incorporation of amide groups but also their accessibility is crucial to obtain enhanced CO₂ sorption and CO₂/N₂ selectivity. Therefore, the MOF with more accessible amide groups (**TMU-24**) shows a CO₂/N₂ selectivity value of ca. 10 (as revealed by breakthrough experiments), which is ca. 500 % and 700 % of the selectivity values observed for the other amide-containing (**TMU-22** and **TMU-23**) and imine-containing (**TMU-6** and **TMU-21**) MOFs.

INTRODUCTION

Microporous metal-organic frameworks (MOFs), constructed from metal-based nodes and polytopic organic ligands, are a promising class of porous materials for carbon capture, separation and storage owing to their very high surface areas, tuneable pore sizes and shapes, and adjustable pore surface functionality.¹⁻³ For these specific applications, it is widely accepted that certain chemical functionalities located at the pore surfaces of MOFs can increase their CO₂ uptake and selectivity.⁴⁻¹⁰ Among these functionalities, [ENREF 6](#) CO₂ has been found to bind at unsaturated metal centres *via* the electron rich terminal oxygen atom¹¹⁻¹³. Also, CO₂ can interact with electron rich Lewis basic groups *via* electron deficient carbon atom.¹⁴ For this purpose, most efforts have been made on the direct and post-synthetic functionalization of MOFs with amine groups.¹⁵⁻¹⁸ More recently, another approach based on the combined optimization of pore size and high charge density has anticipated very promising results.^{4, 19, 20}

Besides the use of amine groups, [ENREF 20](#) the intrinsic characteristics of the amide groups make them also very attractive to establish cooperative

intermolecular interactions with CO₂.²¹ Amide groups possess two types of donor-acceptor affinity sites: the -NH moiety that can act as an electron acceptor (Lewis acid), and the -C=O group that can act as an electron donor (Lewis base); both allowing to establish NH...OCO and NC=O...CO₂ interactions.²²⁻²⁴ In the last few years, the study of some amide-functionalized MOFs has confirmed their potential for selectively adsorb CO₂.^{5, 22, 24-30} For example, Chen, Wang *et al.* have reported that pores decorated with acylamide groups in the Cu(II)-based UTSA-48 MOF promote strong interactions with CO₂ and high selectivity for CO₂ over CH₄.⁵ Recently, Wang *et al.* reported a 3-fold interpenetrated acylamide-MOF that shows higher selective adsorption of CO₂ rather than other gases with a significant isosteric heat.³¹ Similarly, Zaworotko *et al.* found that the decoration of a **rht**-type MOF also with acylamide functions can significantly enhance the CO₂ uptake and the selective adsorption of CO₂ over N₂ in comparison to PCN-61; an isorecticular analogue with acetylene moieties instead of amide groups.²⁴ Remarkably, comparable trends of selectivity have also been observed in other MOFs decorated with acylamide²⁵⁻²⁸ and oxamide²² groups as well as in some

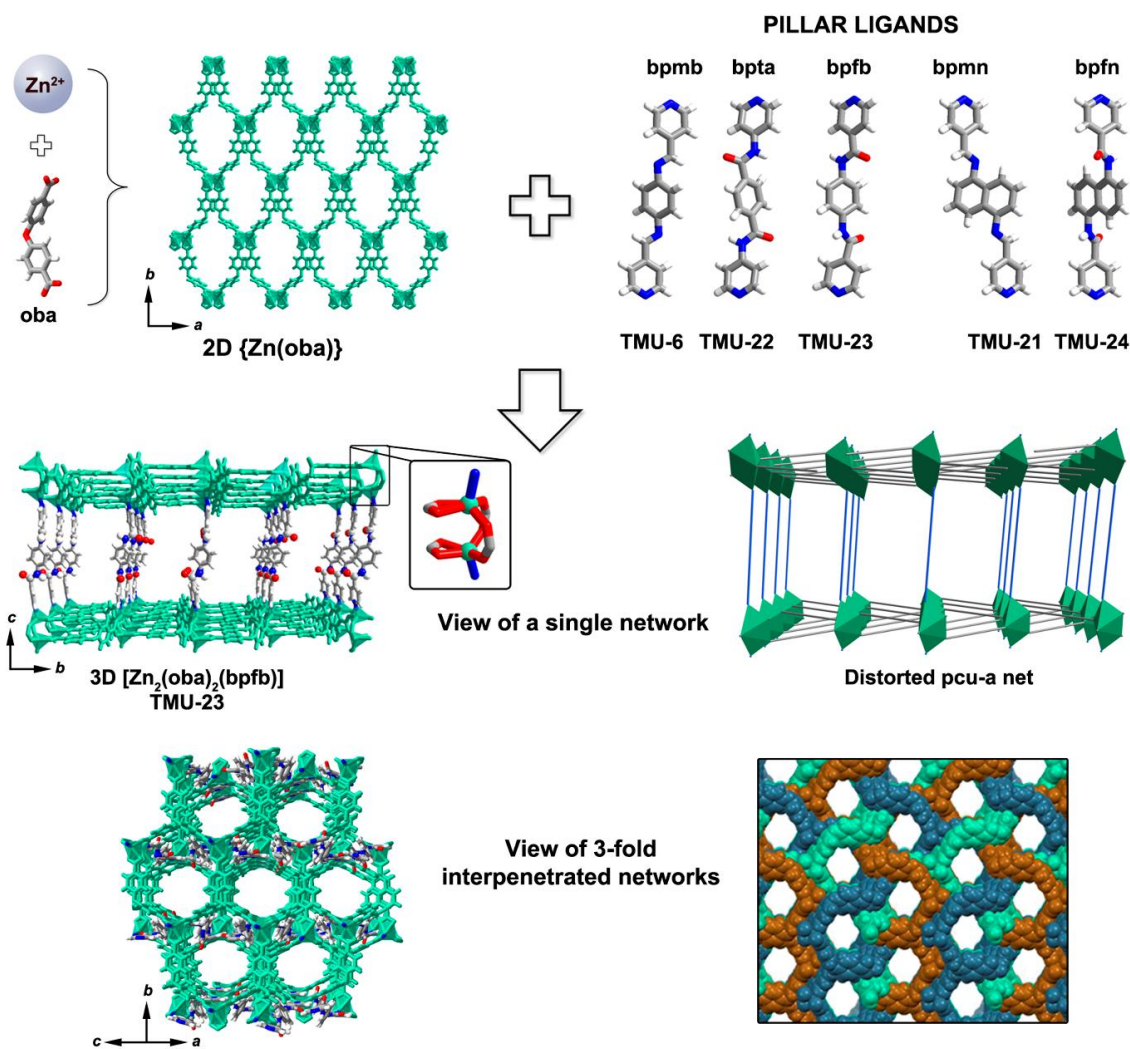

Figure 1. 2D layers formed by the association between Zn(II) ions and oba linkers are further pillared by amide/imine-functionalized dipyridyl-based ligands yielding to 3D-interpenetrated porous **pcu**-MOFs.

recent porous covalent organic frameworks also containing acylamide groups.^{29, 30}

Recent studies reported by us have shown that a series of porous interpenetrated MOFs can be designed by pillaring 2D layers, comprising Zn(II) ions and the V-shaped dicarboxylate ligand 4,4'-oxybisbenzoic acid (H_2oba), with linear dipyridyl-based ligands (Fig. 1).³²⁻³⁴ Following this approach, we found that the pores of the synthesized MOFs can be easily functionalized with the two groups incorporated in the pillar ligands since the pores of these MOFs, which run perpendicular to the $\{\text{Zn}(\text{oba})\}$ layers, are also delimited by these ligands.^{29, 30, 35} For example, the use of the pillar ligands N,N'-bis-(4-pyridylmethylene)-1,4-benzenediamine (bpmb) and its naphthalene analogue N,N'-bis-(4-pyridylmethylene)-1,5-naphthalenediamine (bpmn) recently allowed the formation of two isorecticular 3-fold interpenetrated MOFs

showing pores functionalized with imine groups [called **TMU-6** and **TMU-21** (TMU = Tarbiat Modares University)].^{33, 34} Herein, inspired by this approach and the potential of the amide groups for enhancing the selectivity towards CO_2 , we report the synthesis of three newly acylamide-containing MOFs. The selected pillar ligands are N,N'-bis(4-pyridinyl)-terephthalamide (bpta), N,N'-(1,4-phenylene)diisonicotinamide (bpfb), and N,N'-bis-(4-pyridylformamide)-1,5-naphthalenediamine (bpfm), Figures 1 and S1, which lead to the assembly of: $[\text{Zn}_2(\text{oba})_2(\text{bpta})]\cdot(\text{DMF})_3$ (**TMU-22**; where DMF is N,N-dimethylformamide); $[\text{Zn}_2(\text{oba})_2(\text{bpfb})]\cdot(\text{DMF})_5$ (**TMU-23**), in which the acylamide group is inverted in comparison to **TMU-22**; and $[\text{Zn}_2(\text{oba})_2(\text{bpfm})]\cdot(\text{DMF})_2$ (**TMU-24**), in which the use of the naphthalene analogue also induces that the acylamide groups are more directed towards the pores than in **TMU-22** and **TMU-23** (Figure

2). Importantly, the resulting 3-fold interpenetrated **TMUs-22/-23/-24** are isorecticular to **TMU-6** and **TMU-21**. The similarities (structure and stability) and differences (functional group and accessibility) of these MOFs allow studying the influence of the amide and the imine groups on their N₂ and CO₂ sorption properties as well as on their selective sorption of CO₂ over N₂. More specifically, this latter selectivity was evaluated by performing kinetics and breakthrough experiments for a CO₂/N₂ gas mixture.

EXPERIMENTAL SECTION

Materials and Characterization

The commercially available reagents were used without further purification. Ligands, **TMU-6** and **TMU-21**, were synthesized following reported procedures.^{33,34} See Supporting Information and Figure S1 for synthetic details. Elemental analyses were collected on a CHNS Thermo Scientific Flash 2000 elemental analyser. Powder X-ray diffraction (PXRD) measurements were collected on a Philips X'pert diffractometer with monochromatic Cu-K α radiation ($\lambda_{Cu} = 1.5406 \text{ \AA}$). Thermogravimetric analysis (TGA) were carried out in a Perkin Elmer Pyris 1 under N₂ atmosphere and heating rate of 10 °C/min. Fourier transform infra-red (FT-IR) spectra were recorded on a Bruker Tensor 27FTIR spectrometer equipped with a Golden Gate diamond attenuated total reflection (ATR) cell, in absorption mode at room temperature.

General synthesis of TMU-22, TMU-23 and TMU-24

A mixture of Zn(NO₃)₂·6H₂O (0.297 g, 1 mmol), H₂oba (0.258 g, 1 mmol), and the corresponding amide ligand (0.5 mmol) and DMF (50 mL) was sonicated until all solids were uniformly dispersed (≈ 3 minutes) and divided into 7 glass vials. The vials were heated at 120 °C for 3 days and then cooled to room temperature. Colourless (**TMU-22**) and red-brown (**TMU-23** and **TMU-24**) crystals were obtained as pure phases, washed by DMF, and dried at room temperature.

Data for **TMU-22**. Yield: 44 %. FT-IR (cm⁻¹): 1691 (m), 1595 (vs), 1504 (s), 1395 (vs), 1331 (m), 1298 (m), 1238 (vs), 1160 (vs), 1098 (m), 777 (m), 659 (m), 524 (m). EA on solvent free sample: calcd. (%) for C₄₆H₃₀N₄O₁₂Zn₂: C, 57.46; H, 3.15; N, 5.83; found: C, 57.50; H, 3.11; N, 5.74.

Data for **TMU-23**. Yield: 36 %. FT-IR (cm⁻¹): 1673 (vs), 1597 (vs), 1540 (m), 1510 (m), 1399 (vs), 1309 (m), 1220 (vs), 1159 (s), 1088 (m), 1067 (m), 1014 (m), 801 (m), 658 (m), 524 (m). EA on solvent free sample: calcd. (%) for C₄₆H₃₀N₄O₁₂Zn₂: C, 57.46; H, 3.15; N, 5.83; found: C, 57.00; H, 3.10; N, 5.65.

Data for **TMU-24**. Yield: 38 %. IR (cm⁻¹): 1667 (vs), 1595 (vs), 1570 (m), 1505 (s), 1386 (vs), 1235(s), 1158 (vs), 1089 (m), 1065 (m), 1015 (m), 878 (m), 659 (m), 522 (m). EA on solvent free sample: calcd. (%) for C₅₀H₃₂N₄O₁₂Zn₂: C, 59.37; H, 3.19; N, 5.54; found: C, 57.10; H, 3.12; N, 5.01.

Crystallography

Crystallographic data for **TMU-22** and **TMU-23** were collected at 100 K at XALOC beamline at ALBA synchrotron³⁶ ($\lambda = 0.79474 \text{ \AA}$ and 0.82653 \AA , respectively). Data were indexed, integrated and scaled using the XDS³⁷ and IMOSFLM³⁸ programs. Absorption correction was not applied. SCXRD for **TMU-24** was collected at 293 K on a Bruker AXS SMART Apex diffractometer using graphite monochromated Mo-K α radiation ($\lambda = 0.71073 \text{ \AA}$) and were corrected for Lorentz and polarization effects. The frames were integrated with the Bruker SAINT³⁹ software package. Absorption corrections were applied using the program SADABS⁴⁰ giving max./min. transmission factors of 1.000/0.270. The structures were solved by direct methods and subsequently refined by correction of F² against all reflections, using SHELXS2013⁴¹ and SHELXL2013⁴² within the WinGX package.⁴³ All non-hydrogen atoms were refined with anisotropic thermal parameters by full-matrix least-squares calculations on F² using the program SHELXL2013. Hydrogen atoms were inserted at calculated positions and constrained with isotropic thermal parameters. In **TMU-24**, the carbonyl group of the N,N-ligand is distorted in two positions with 55 % and 45 % of occupancy. The structures contain some disorder molecules. Attempts to adequately model of disordered DMF molecules (40 electrons) were unsatisfactory; therefore the PLATON/SQUEEZE⁴⁴ routine has been applied to mask out the disordered electron density. The residual electron density was assigned to 3, 5 and 1 molecules of DMF in **TMU-22** (509 electrons per unit cell), **TMU-23** (876 electrons located per unit cell) and in **TMU-24** (384 electrons per unit cell). Crystallographic and refinement data, and the main bond distances and angles are listed in Table 1 and Tables S1-3.

Low-Pressure Sorption Measurements

Volumetric N₂ and CO₂ sorption isotherms were collected at 77 K (N₂) and 203 K, 258 K, 273 K, 288 K and 298 K (CO₂) using an ASAP 2020 HD (Micromeritics). Temperature was controlled by using a liquid nitrogen bath (77 K) or a Lauda Proline RP 890 chiller (203 K – 298 K). The total pore volumes (V_t) were calculated at P/Po = 0.95 (N₂) and at 760 torr (CO₂).

Kinetics of adsorption

Kinetic evaluation of the sorbents was performed at 298 K in a home-made glass manometric adsorption equipment using pure gas components (CO₂ and N₂). This equipment is constituted by a manifold of a well-known volume (to define the initial gas dose), a sample holder containing the adsorbent and a pressure transducer. Prior to the adsorption experiment, the samples were degassed under vacuum at the activation temperature used for single gas sorption experiments. The initial pressure in the manifold was defined at 500 mbar for all adsorbates. Once equilibrated, the manifold was expanded to the sample holder, pressure readings being recorded every second and lasting for ten minutes. Moreover, the sample holder was immersed in a temperature-controlled water bath at 298 K to minimize any heat effect due to the adsorption process itself.

Breakthrough measurements

Breakthrough curve experiments for different mixture of gases were carried out using a column. The samples powders were packed in the middle part of the column. Here, the samples masses used were 0.30 g. The flow rates of all gases were controlled by mass flow controllers. Before the measurement, the samples were activated at the desired temperature for 2 h using a He total flow of 50 mL.min⁻¹.

The gas stream from the outlet of the column was analysed online with a mass spectrometer.

The CO₂/N₂ selectivities (σ) of samples were evaluated by the following equation:

$$\sigma = \frac{\left(\frac{q_{CO_2}}{p_{CO_2}} \right)}{\left(\frac{q_{N_2}}{p_{N_2}} \right)}$$

where q_i is the adsorption capacity of i component, p_i is the partial pressure of i component.

The amount adsorbed for each gas was calculated by the integration of the breakthrough curves. For this purpose, breakthrough experiments with H₂ (not adsorbed in these materials), have been performed using the same bed and the same flows. Then, the H₂ breakthrough curve has been used to calculate the time zero and more importantly to consider the shape of the breakthrough in the integration. The amount of gas adsorbed was the different between the shape of the CO₂ or N₂ breakthrough and the H₂ breakthrough. Thus, the dispersion and the very small pressure drop can be considered.

Results and discussion

Synthesis and crystal structures

TMUs-22/-23/-24 were synthesized following the same pillaring strategy reported for TMU-6 and TMU-21.^{33,34} Solvothermal reactions between $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, H_2oba and the correspondent pillar ligand in DMF at 120 °C for 3 days produced prismatic crystals of TMUs-22/-23/-24 suitable for single-crystal X-ray diffraction analyses. The simulated (derived from the single crystal structures) and experimental powder X-ray diffraction (PXRD) patterns were consistent (Figure S2), confirming that all synthesized MOFs can be obtained as pure phases; as also corroborated by Fourier transformed infrared spectroscopy and elemental analysis (performed on the activated samples, *vide infra*).

TMU-22 and TMU-23 crystallize in the monoclinic $P2_1/n$ and $P2_1/c$ space groups, respectively (Table 1). They are neutral 3-fold interpenetrated MOFs formed by $\{\text{Zn}(\text{oba})\}$ layers connected through the N,N'-pillar ligands. As in TMU-6, their basic unit is a dinuclear zinc cluster, in which both Zn(II) centres are penta-coordinated to four carboxylate O atoms from three fully deprotonated oba ligands and to one N atom from the N,N'-donor ligand (Figure 1). The geometry around the metal centres can be described as a distorted square pyramid, with Addison parameter⁴⁵ τ values in the range of 0.35-0.49. In these structures, each nonlinear dicarboxylate oba ligand is coordinated to three Zn(II) centres forming the $\{\text{Zn}(\text{oba})\}$ layers along the *ab* plane. Because of the dinuclear nature of the metal cluster, these layers are formed by two sheets of parallel oba ligands that form π - π stacking interactions between them (Figure 1; Tables S4, S5). These $\{\text{Zn}(\text{oba})\}$ layers are then pillared by the linear acylamide-functionalized ligands, extending the structure in three dimensions. It is important to mention here that, due to the conformational flexibility of both oba and bpta ligands, TMU-22 is a supramolecular conformational isomer of a reported MOF.³¹ Although both compounds are 3-fold interpenetrated, they still possess apparent 1D pore channels ($\approx 7.0 \times 6.5$ Å and $\approx 6.8 \times 6.4$ Å -including van der Waals (vdW) radii- for TMU-22 and TMU-23, respectively) running along the $\langle 101 \rangle$ direction and noticeable free space (33 % for TMU-22 and 32 % for TMU-23), comparable to the values found for TMU-6 ($\approx 8.1 \times 7.4$ Å; and 33 % free space)⁴⁶ (Figures 1 and S3-5). The channels are filled with disordered guest solvent molecules, squeezed due to thermal disorder.

TMU-24 crystallizes in the monoclinic $C2/c$ space group (Table 1), showing a crystal structure isorecticular to those of TMUs-6/-21/-22/-23. Thus, it also consists on a 3-fold interpenetrated network that exhibits 1D pore channels of $\approx 6.7 \times 5.5$ Å (free space = 30 %) functionalized with acylamide groups. These values are similar to those exhibited by its imine-functionalized TMU-21 analogue, which shows a pore size of $\approx 8.2 \times 7.0$ Å and a free space of 30 %.⁴⁶ (Figures S6-7).

Here it is very important to note that, even though TMUs-22/-23/-24 are isorecticular, their acylamide groups do not show the same orientation on the pore surfaces (Figure 2b,c,e) as well as do not participate in the same number of supramolecular interactions between the interpenetrated networks (Tables S4-6). In TMU-23, all donor -N-H and acceptor -C=O groups of the two acylamide groups per pillar ligand establish H-bonds and N-H... π interactions with the other two networks forming the 3-fold interpenetrated structure. In TMU-22, each donor -NH moiety of the two acylamide groups per pillar ligand establishes H-bonds with carboxylate groups of the other networks, whereas the two acceptor -C=O groups do not participate in H-bonds. In TMU-24, only one of the two acylamide groups forms H-bonds. Interestingly, the other acylamide group is pointing towards the pores so that it does not participate in direct H-bonds with the other networks (Figure 2e). Altogether makes this acylamide group easily accessible to potential interactions with CO_2 guest molecules. Contrariwise, even though all the other H-bonded acylamide groups of TMUs-22/-23/-24 are located on the surfaces of the pores, they are not directly pointing towards the channels, and therefore they are in principle less accessible to guest molecules.

Topology

Topological analysis performed with TOPOS⁴⁷ revealed that all the studied MOFs show the same 3-fold interpenetrated, 6-connected net with **pcu** topology (Figure 1). The **pcu** topology is ubiquitous in MOFs, including the iconic MOF-5.⁴⁸ Here, it is worth to mention that the **pcu** net is edge-transitive with cubic symmetry and $Pm-3m$ space group. However, in the present case, the overall symmetry of TMUs-22/-23/-24 decreased to monoclinic (Table 1). This symmetry decrease is attributed to the fact that the points of extension of the Zn(II) dimer do not match with the vertices of the perfect octahedron required to produce highly symmetrical **pcu**-MOFs (Figure 1). In addition, the use of a pillaring strategy with mixed ligands (including the flexible oba and pillar N,N'-ligands) also forces the symmetry to differ from that of MOF-5.

Thermal stability

The TGA diagrams of all as-synthesized materials revealed a first weight loss of 16.08 % (room temperature (r.t.)-300 °C) for TMU-6, 13.71 % (80-325 °C) for TMU-21, 9.93 % (100-240 °C) for TMU-22, 15.16 % (r.t.-300 °C) for TMU-23, and 15.46 % (r.t.-325 °C) for TMU-24. In all cases, this weight loss was attributed to the removal of all guest solvent molecules. Decomposition of all materials starts at around 400 °C, confirming their high thermal stability (Figure S8).

Activation process

All compounds were activated using a very similar protocol that started with a solvent-exchange step. TMUs-6/-21 and TMUs-22/-23/-24 were immersed in acetonitrile and dichloromethane, respectively, for 3 days, during which the solvent was exchanged once daily. Note here that previous stability tests showed that all synthesized MOFs were stable in these solvents (Figure S9) for at least 24 h at r.t. Then, each MOF was evacuated for 12 h under vacuum at 150 °C prior to gas sorption measurements. It is noteworthy that PXRD diagrams collected after the sorption studies confirm that the frameworks retain their crystallinity and remained unaltered after both processes (Figure S10). These observations were further corroborated by elemental analysis and TGA, in which only the weight losses around 400 °C corresponding to their decomposition were observed (Figure S8).

Nitrogen sorption at 77 K

N₂ isotherm at 77 K on TMU-22 showed a characteristic type I behaviour of microporous materials, as expected from its crystal structure (BET area (A_{BET}) = 680 m².g⁻¹; pore volume (V_t) = 0.28 cm³.g⁻¹). Contrariwise, TMU-21, TMU-23 and TMU-24 were found to be non-porous materials (negligible N₂ uptake). In the case of TMU-6, it showed much lower porosity than that expected from its crystal structure (A_{BET} = 150 m².g⁻¹; V_t = 0.08 cm³.g⁻¹) (Table 2, Figure S11). Thus, all activated compounds, except TMU-22, reveal a “N₂-phobic” behavior.⁴⁹⁻⁵² We reasoned that this behaviour could be due to the existence of different structural rearrangements depending on the MOF during sorption or when exposed to cryogenic temperatures and/or under vacuum, reducing/preventing access to the porosity. Indeed, similar temperature dependent behaviours are already well-known in soft materials such as in MIL-53 (Al).⁵³ However, other factors cannot be fully excluded, such as the existence of strong interactions between N₂ and the channel walls at 77 K that hinder diffusion into the material.⁵⁴

Table 2. Summary of BET areas, total pore volumes and CO₂ uptakes observed for TMUs-6/-21-24.

| MOF | A_{BET} (m ² .g ⁻¹) (N ₂ , 77 K) | Total V_t (cm ³ .g ⁻¹) (N ₂ ^a / CO ₂ ^b) | Theo V_t (cm ³ .g ⁻¹) ^c | CO ₂ uptake ^b (mmol.g ⁻¹) (203 K) |
|--------|---|---|--|---|
| TMU-6 | 150 | 0.08 / 0.32 | 0.22 | 9.0 |
| TMU-21 | ≈ 0 | ≈ 0 / 0.16 | 0.25 | 4.5 |

CO₂ sorption at various temperatures and heats of adsorption

Contrariwise to the adsorption of N₂, the CO₂ sorption isotherms at various temperatures revealed that all of them are porous (Figures 3a and S12a-16a). CO₂ uptake at 203 K were calculated to be 9.0 mmol.g⁻¹, 4.5 mmol.g⁻¹, 7.2 mmol.g⁻¹, 7.2 mmol.g⁻¹ and 6.3 mmol.g⁻¹ for TMU-6, TMU-21, TMU-22, TMU-23 and TMU-24, respectively (Table 2). The observed pore volumes (at 760 torr) were: 0.32 cm³.g⁻¹ (TMU-6), 0.16 cm³.g⁻¹ (TMU-21), 0.25 cm³.g⁻¹ (TMU-22), 0.27 cm³.g⁻¹ (TMU-23) and 0.22 cm³.g⁻¹ (TMU-24). These pore volumes calculated from the CO₂ adsorption data are in agreement with the theoretical values extracted from the crystal structures. The variations observed can be attributed to small structural changes widely observed in such interpenetrated sorbents.^{35, 55-57}

Figure 3. (a) Heats of adsorption of CO₂ and (b) CO₂ sorption isotherms at 298 K for TMUs-6/-21-24.

Isosteric heats of adsorption of CO₂ (Q_{st}) were calculated from the isotherms collected at different temperatures (Table 2 and Figures S12-16). The two acylamide-functionalized **TMU-24** and **TMU-22** exhibited the highest Q_{st} for CO₂, from 24 to 26 kJ·mol⁻¹ and 23 to 24 kJ·mol⁻¹, respectively. The different Q_{st} for CO₂ between **TMU-24**, **TMU-22**, and **TMU-23** can be attributable to the different accessibility of their acylamide groups and to the different number of supramolecular interactions in which they are involved (*vide supra*).

CO₂/N₂ separation properties

In light of the porosity of the materials for CO₂ and their apparent low affinity for N₂, we further investigated their potential for CO₂/N₂ separation by performing kinetics experiments (Figures 4 and S17). As expected, the highest selectivity (σ) for CO₂ over N₂ was observed for **TMU-24** ($\sigma = 14.1$, Table 3); which is the material exhibiting the highest Q_{st} of CO₂ and with the most accessible acylamide groups pointing towards the porous channels. Overall, the CO₂/N₂ selectivity of **TMU-24** estimated from kinetics experiment is *ca.* 70 % higher than for the other materials of the family.

These results were further confirmed by breakthrough experiments with CO₂/N₂ gas mixture (Figures 5 and S18). Once again, **TMU-24** performed much better than its isorecticular variants, with a CO₂/N₂ selectivity of 10.0 at r.t. for an equimolar CO₂/N₂ gas mixture (Figure 5). This value represents 700 % of the selectivity found in similar conditions for its imine analogue **TMU-21** ($\sigma = 1.4$). It also performs better than **TMU-22** and **TMU-23**, the other acylamide containing MOFs with less accessible functional groups. Indeed, the selectivity of **TMU-24** is 500 % and 580 % the selectivity of **TMU-22** and **TMU-23**, respectively. Therefore, not only the incorporation of amide functional groups in the frameworks but also their accessibility for the CO₂ guest molecules is crucial to enhance the CO₂/N₂ selectivity. This observation was further confirmed in more realistic gas mixture conditions (CO₂:N₂ = 1:9), in which **TMU-24** was still found to perform well with a selectivity of 4.6 (Figure 5). It is important to remark that the CO₂ adsorption capacity found in the breakthrough experiment at r.t. (≈ 0.65 mmol·g⁻¹) for **TMU-24** is slightly lower than the one extracted from the isotherm at 500 mbar and r.t. (≈ 0.85 mmol·g⁻¹). This feature can be attributed to a small amount of N₂ adsorbed in these conditions (298 K and gas mixture).

Table 3 Summary of CO₂ separation properties in TMUs-6/-21/-22/-23/-24.

| MOF | Q_{st} of CO ₂ (kJ·mol ⁻¹) | Selectivity (Kinetics) | Selectivity (Breakthrough, CO ₂ :N ₂ 1:1) |
|-----|--|---------------------------|--|
|-----|--|---------------------------|--|

| | | | |
|---------------|-------|------|------|
| TMU-6 | 17-14 | 8.2 | 1.8 |
| TMU-21 | 18-20 | 8.2 | 1.4 |
| TMU-22 | 23-24 | 8.6 | 2.0 |
| TMU-23 | 12-18 | 8.2 | 1.7 |
| TMU-24 | 24-26 | 14.1 | 10.0 |

Figure 4. Adsorption kinetics of CO₂ and N₂ for **TMU-24** at 298 K (initial manifold pressure 500 mbar).

Figure 5. CO₂/N₂ Breakthrough separation curves at 298 K for TMU-24 with total flow of 5 mL.min⁻¹ for CO₂:N₂ = 1:1 (a) and 25 mL.min⁻¹ for 1:9 (b).

CONCLUSIONS

We successfully synthesized three novel, 3-fold interpenetrated pcu-MOFs containing acylamide functional groups (TMU-22, TMU-23 and TMU-24), isorecticular to the recently reported imine-containing MOFs, TMU-6 and TMU-21. The study of their sorption properties revealed that the insertion of amide functional groups in MOFs does not necessarily induce a noticeable improvement of the CO₂/N₂ separation properties. Indeed, another aspect that needs to be addressed is the accessibility of the functional groups, especially in interpenetrated frameworks. If neglected, it could jeopardize the efficiency of MOFs functionalization, as illustrated by the performance of TMU-22 and TMU-23, two acylamide-functionalized analogues of the parent imine-functionalized TMU-6; that all these three MOFs show negligible difference of the selectivity. This demonstrates the needs for smart materials design approaches, further confirmed by the deliberate alteration

of the pore shape of TMU-24 using a bulky, central naphthalene core. This resulted in better accessibility of the acylamide groups, leading into a 70 % improvement of CO₂/N₂ selectivity according to kinetics studies (from 8.2 to 14.1 for TMU-21 and TMU-24, respectively). Moreover, a dramatic increase of the selectivity was obtained from breakthrough experiments. The CO₂/N₂ selectivity for TMU-24 corresponds to ca. 700 % of this imine- containing analogue, TMU-21. Moreover, its selectivity is ca. 500 % and 580 % of TMU-22 and TMU-23, two isorecticular, amide containing MOFs with less accessible functional groups.

The influence of the amide groups in the CO₂/N₂ selectivity of a series of isorecticular, interpenetrated metal-organic frameworks.

Vahid Safarifard, Sabina Rodríguez-Hermida, Vincent Guillerm, Inhar Imaz, Mina Bigdeli, Alireza A. Tehrani, Jordi Juanhuix, Ali Morsali,* Mirian E. Casco, Joaquín Silvestre-Albero, Enrique V. Ramos-Fernandez and Daniel Maspoch*

The accessibility of amide functional groups within MOF structures is crucial to obtain enhanced CO₂ sorption and CO₂/N₂ selectivity.
